Class 13: RNASeq with DESeq2

Isabel Hui - A16887852

Today we will analyze some RNASeq data from Himes et al. on the effects of dexamethasone (dex), a synthetic glucorticoid steroid on airway smooth muscle cells (ASM).

Data import

```
counts <- read.csv("airway_scaledcounts.csv", row.names=1)
metadata <- read.csv("airway_metadata.csv")

#head(counts)

#head(metadata)

Q1. How many genes are in this dataset?

nrow(counts)

[1] 38694

Q2. How many 'control' cell lines do we have?

sum(metadata$dex == "control")

[1] 4

table(metadata$dex)</pre>

control treated

4 4
```

Toy Differential Expression Analysis

Calculate the mean per gene count values for all "control" samples (i.e. columns in counts), do the same for "treated", and then compare them.

1. Find all "control" values/columns in counts.

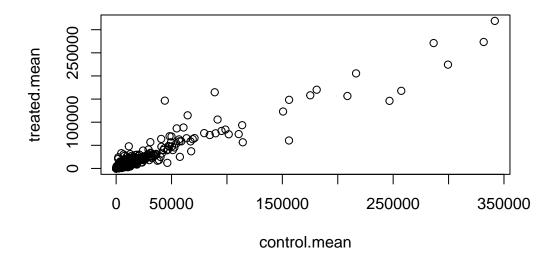

```
control.inds <- metadata$dex == "control"
control.counts <- counts[,control.inds]</pre>
```

2. Find the mean per gene across all control columns.

```
control.mean <- apply(control.counts, 1, mean)</pre>
```

3. Do the same steps to find the treated.mean values.

```
treated.mean <- apply(counts[ ,metadata$dex == "treated"], 1, mean)
meancounts <- data.frame(control.mean, treated.mean)
plot(meancounts)</pre>
```

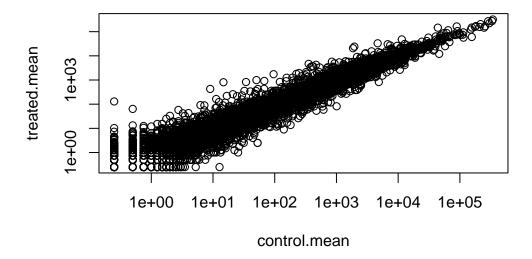

It would help to scale since all of the data points seem to be congested.

plot(meancounts, log="xy")

Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted from logarithmic plot

Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted from logarithmic plot

We most frequently use log2 transformations for this type of data.

log2(10/10)

[1] 0

log2(20/10)

[1] 1

log2(10/20)

[1] -1

log2(10/40)

[1] -2

These $\log 2$ values make the interpretation of "fold-change" a little easier and a rule-of-thumb in the fild is a $\log 2$ fold-change of +2 or -2 is where we start to pay attension.

```
log2(40/10)
```

[1] 2

Let's calculate the log2(fold-change) and add it to our meancounts data.frame.

meancounts\$log2fc <- log2(meancounts\$treated.mean/meancounts\$control.mean)
head(meancounts)</pre>

log2fc	${\tt treated.mean}$	${\tt control.mean}$	
-0.45303916	658.00	900.75	ENSG0000000003
NaN	0.00	0.00	ENSG0000000005
0.06900279	546.00	520.50	ENSG00000000419
-0.10226805	316.50	339.75	ENSG00000000457
-0.30441833	78.75	97.25	ENSG00000000460
-Inf	0.00	0.75	ENSG00000000938

```
to.rm <- rowSums(meancounts[,1:2]==0) > 0
mycounts <- meancounts[!to.rm,]</pre>
```

Q. How many genes do I have left after this zero count filtering?

```
nrow(mycounts)
```

[1] 21817

Q. How many genes are "up" regulated upon drug treatment at a threshold of +2 log2-fold-change?

- 1. I need to extract the log2fc values.
- 2. I need to find those that are above +2.
- 3. Count them.

```
sum(mycounts$log2fc > 2)
```

[1] 250

Q. How many genes are "down" regulated upon drug treatment at a threshold of -2 log2-fold-change?

```
sum(mycounts$log2fc < (-2))</pre>
```

[1] 367

Wow hold on we are missing the stats here. Is the difference in the mean counts significant? Let's do this analysis the right way with stats and use the **DESeq** package.

DESeq Analysis

```
library(DESeq2)
```

The first function that we will use will setup the data in the way (format) DESeq wants it.

converting counts to integer mode

Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in design formula are characters, converting to factors

The function in the package is called DESeq() and we can run it on our dds object.

dds <- DESeq(dds)</pre>

estimating size factors

estimating dispersions

gene-wise dispersion estimates

mean-dispersion relationship

final dispersion estimates

fitting model and testing

I will get the results from dds with the results() function:

res <- results(dds) head(res)</pre>

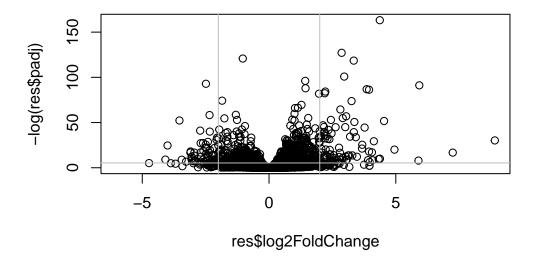

log2 fold change (MLE): dex treated vs control
Wald test p-value: dex treated vs control

DataFrame with 6 rows and 6 columns

DataFrame with 6 rows and 6 columns								
	baseMean	${\tt log2FoldChange}$	lfcSE	stat	pvalue			
	<numeric></numeric>	<numeric></numeric>	<numeric></numeric>	<numeric></numeric>	<numeric></numeric>			
ENSG00000000003	747.194195	-0.3507030	0.168246	-2.084470	0.0371175			
ENSG00000000005	0.000000	NA	NA	NA	NA			
ENSG00000000419	520.134160	0.2061078	0.101059	2.039475	0.0414026			
ENSG00000000457	322.664844	0.0245269	0.145145	0.168982	0.8658106			
ENSG00000000460	87.682625	-0.1471420	0.257007	-0.572521	0.5669691			
ENSG00000000938	0.319167	-1.7322890	3.493601	-0.495846	0.6200029			
	padj							
	<numeric></numeric>							
ENSG00000000003	0.163035							
ENSG00000000005	NA							
ENSG00000000419	0.176032							
ENSG00000000457	0.961694							
ENSG00000000460	0.815849							
ENSG00000000938	NA							

Make a common overall results figure from this analysis. This is designed to keep out inner biologist and inner stats nerd happy—it is plot fold-change vs. P-value.

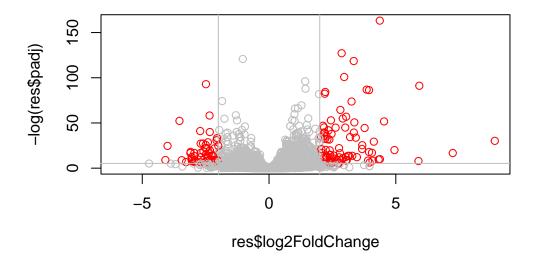

```
plot(res$log2FoldChange, -log(res$padj))
abline(v=c(-2,2), col="gray")
abline(h= -log(0.005), col="gray")
```

Add some color to this plot:

```
mycols <- rep("gray", nrow(res))
mycols[res$log2FoldChange > 2] <- "red"
mycols[res$log2FoldChange < -2] <- "red"
mycols[res$padj > 0.005] <- "gray"

plot(res$log2FoldChange, -log(res$padj), col = mycols)
abline(v=c(-2,2), col="gray")
abline(h= -log(0.005), col="gray")</pre>
```

I want to save my results to date out to disc.

```
write.csv(res, file = "myresults.csv")
```

We will pick this up the next class day and add **annotation** (i.e. what are these genes of interest) and do **pathway analysis** (what biology) are they known to be involved with.

head(res)

```
log2 fold change (MLE): dex treated vs control
Wald test p-value: dex treated vs control
DataFrame with 6 rows and 6 columns
```

ENSG000000000938 NA
```

Annotation

I need to translate our gene identifiers "ENSG000..." into gene names that the rest of the world can understand.

To this "annotation" I will use the **AnnotationDbi** package. I can install this with BiocManager::install()

```
library(AnnotationDbi)
library(org.Hs.eg.db)
```

```
columns(org.Hs.eg.db)
```

```
[1] "ACCNUM"
                    "ALIAS"
                                    "ENSEMBL"
                                                    "ENSEMBLPROT"
                                                                    "ENSEMBLTRANS"
 [6] "ENTREZID"
                    "ENZYME"
                                    "EVIDENCE"
                                                    "EVIDENCEALL"
                                                                    "GENENAME"
[11] "GENETYPE"
                    "GO"
                                    "GOALL"
                                                    "IPI"
                                                                    "MAP"
                                    "ONTOLOGYALL" "PATH"
[16] "OMIM"
                    "ONTOLOGY"
                                                                    "PFAM"
[21] "PMID"
                    "PROSITE"
                                    "REFSEQ"
                                                    "SYMBOL"
                                                                    "UCSCKG"
[26] "UNIPROT"
```

I will use the mapIds() function to "map" my identifiers to those from different databases. I will go between "ENSEMBL" and "SYMBOL" (and then after "GENENAME").

^{&#}x27;select()' returned 1:many mapping between keys and columns

```
#head(res)
```

Add "GENENAME":

'select()' returned 1:many mapping between keys and columns

Add

'select()' returned 1:many mapping between keys and columns

log2 fold change (MLE): dex treated vs control

head(res)

```

Save our annotated results object.

```
write.csv(res, file = "results_annotated.csv")
```

Pathway Analysis

Now that we have our results with added annotation we can do some pathway analysis.

Let's use the **gage** package to look for KEGG pathways in our results (genes of interest). I will also use the **pathview** package to draw little pathway figures.

```
#|message: false
library(pathview)
```

Pathview is an open source software package distributed under GNU General Public License version 3 (GPLv3). Details of GPLv3 is available at http://www.gnu.org/licenses/gpl-3.0.html. Particullary, users are required to formally cite the original Pathview paper (not just mention it) in publications or products. For details, do citation("pathview") within R.

The pathview downloads and uses KEGG data. Non-academic uses may require a KEGG license agreement (details at http://www.kegg.jp/kegg/legal.html).

```
library(gage)

                                "7084"
                                          "7172"
                                                   "7363"
                                                            "7364"
                                                                     "7365"
[33] "574537" "64816"
[41] "7366"
              "7367"
                       "7371"
                                "7372"
                                          "7378"
                                                   "7498"
                                                            "79799"
                                                                     "83549"
[49] "8824"
              "8833"
                       "9"
                                "978"
```

What **gage** wants as input is not my big table/data.frame of results. It just wants a "vector of importance". For RNASeq data like we have this is our log2FC values...

```
foldchanges = res$log2FoldChange
names(foldchanges) = res$entrez
head(foldchanges)
```

```
7105 64102 8813 57147 55732 2268 -0.35070302 NA 0.20610777 0.02452695 -0.14714205 -1.73228897
```

Now, let's run the gage pathway analysis.

```
#Get the results
keggres = gage(foldchanges, gsets = kegg.sets.hs)
```

What is in this keggres object?

```
attributes(keggres)
```

\$names

[1] "greater" "less" "stats"

```
head(keggres$less, 3)
```

```
p.geomean stat.mean
                                                                 p.val

```

Let's use the pathview package to look at one of these highlighted KEGG pathways with our genes highlighted. "hsa05310 Asthma"

pathview(gene.data=foldchanges, pathway.id="hsa05310")

'select()' returned 1:1 mapping between keys and columns

Info: Working in directory /Users/izzy/R/Class 13

Info: Writing image file hsa05310.pathview.png
